INTRODUCTION

The purpose of this report is to introduce the Travel Demand Forecasting (TDF) model built for Santa Monica's Land Use and Circulation Element (LUCE) update. This report describes the model development process in general, and how this process was applied to develop the City of Santa Monica model, including the sources of data used to develop key model inputs.

GENERAL DISCUSSION OF THE TDF MODEL

This section summarizes the answers to commonly asked questions related to TDF models and how the City can use a TDF model.

What is a TDF model?

A TDF model is a computer program that simulates traffic levels and travel patterns for a specific geographic area. The program consists of input files that summarize the area's land uses, street network, travel characteristics, and other key factors. Using this data, the model performs a series of calculations to determine the amount of trips generated, the beginning and ending location of each trip, and the route taken by the trip. The model's output includes projections of traffic volumes on major roads, and peak hour turning movements at certain key intersections.

How is a TDF model useful?

The City TDF model will be a valuable tool for preparing long-range transportation planning studies, such as Santa Monica's General Plan Update. The travel model will be used to estimate the average daily and peak hour traffic volumes on the major roads in response to future land use, transportation infrastructure, and policy assumptions, and form a consistent basis by which to analyze the different potential land use scenarios. Additionally, using these traffic projections, transportation improvements will be identified to accommodate the changing traffic patterns associated with the General Plan's preferred land use alternative.

How do we know if the TDF model is accurate?

To be deemed accurate for projecting traffic volumes in the future, a model must first be calibrated to a year in which actual land use data and traffic volumes are available and well documented. A model is accurately calibrated when it replicates the actual traffic counts on the major roads within certain ranges of error established in *Travel Forecasting Guidelines* (Caltrans, 1992) and it demonstrates stable responses to varying levels of inputs. The Santa Monica model has been calibrated to 2008 base year conditions using actual traffic counts, census data, and land use data surveyed and compiled by City staff.

Is the City of Santa Monica TDF model consistent with standard practices?

The City of Santa Monica model is consistent in form and function with standard travel forecasting models used in transportation planning. The model includes a land use/trip generation module, a gravity-based trip distribution model, and a capacity-restrained equilibrium traffic assignment process. The travel model utilizes Version 5.0 of the TransCAD Transportation GIS software, which is consistent with many of the models used by local jurisdictions in California and throughout the nation. The Southern California Association of Governments (SCAG), the metropolitan planning organization (MPO) for Southern California, maintains their current regional travel demand model in TransCAD.

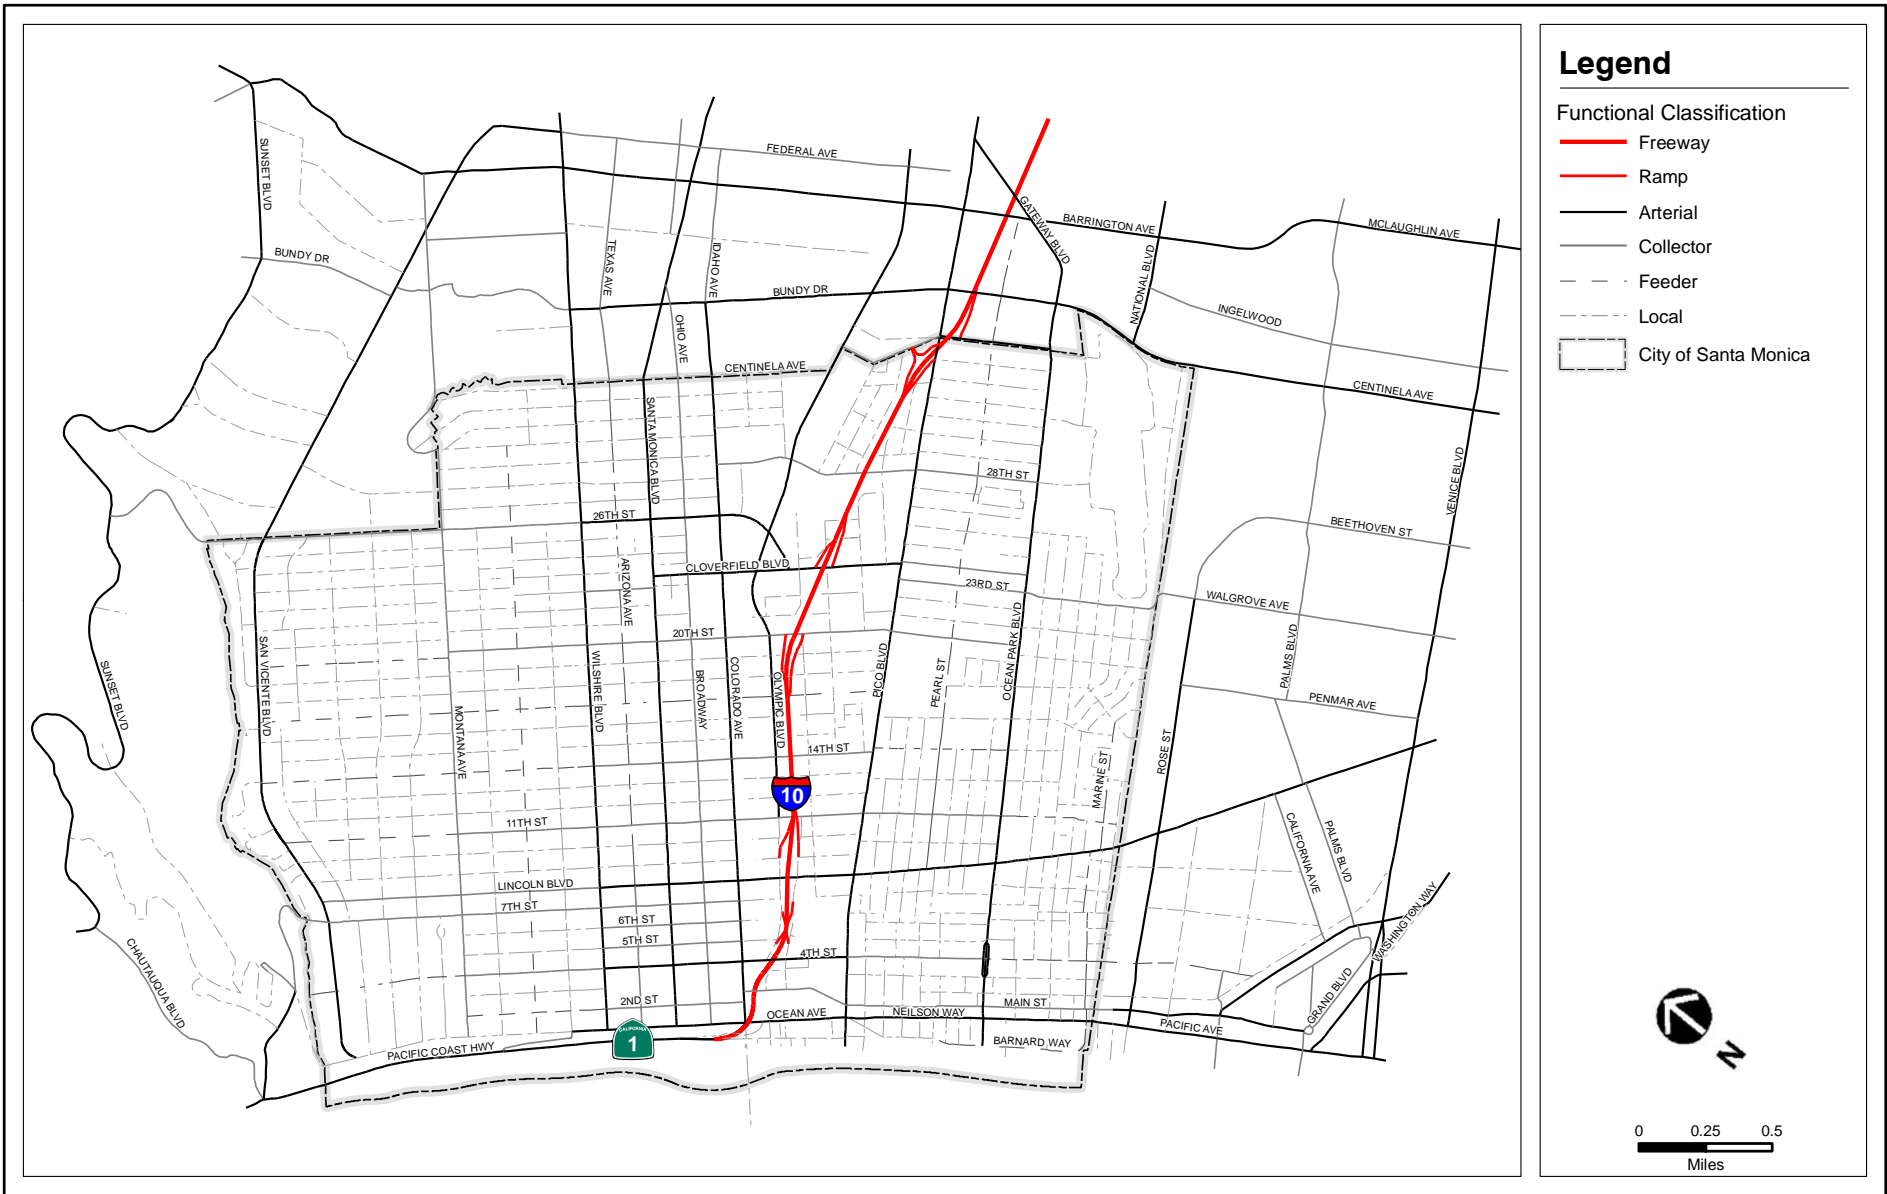

How can the TDF model be used?

The TDF model can be used for many purposes related to the planning and design of the City's transportation system. The following is a partial listing of the potential uses of the TDF model:

- To update the land use and circulation elements of the General Plan
- To conduct a city-wide traffic impact fee program
- To evaluate the traffic impacts of area-wide land use plan alternatives
- To evaluate the shift in traffic resulting from a roadway improvement
- To evaluate the traffic impacts of land development proposals
- To determine trip distribution patterns of larger land development proposals
- To support the development of transportation sections of Environmental Impact Reports (EIRs)
- To support the preparation of project development reports for Caltrans

STUDY AREA AND STREET NETWORK

Figure 1 shows the study area for the City travel demand forecasting model. The model area encompasses the City of Santa Monica and neighboring areas in the City of Los Angeles that have high levels of interaction with Santa Monica. The study area contains all areas that may experience land use changes under *Santa Monica LUCE* and the LUCE alternatives.

SUMMARY OF THE INPUT DATA

DATA COLLECTION

A data collection effort was undertaken at the outset of the *Santa Monica LUCE* process. Data sources include SCAG for street network and regional travel data, Caltrans and the City of Santa Monica for traffic count data, and the City of Santa Monica for land use, and street network data.

LAND USE DATA

Land use data is one of the primary inputs to the Santa Monica model, and this data is instrumental in estimating trip generation. The model's primary source of land use data is the City's parcel-level land use database (maintained in a GIS format). This database provides information on how much development currently exists within each traffic analysis zone (TAZ) (discussed below). The City's land use data is supplemented by SCAG TAZ-based data for areas in the City of Los Angeles bordering the City of Santa Monica.

Land use in the model is divided into a variety of residential and non-residential categories. The City of Santa Monica model employs 30 land use data categories to describe land use in the City, as shown in Table 1.

TRAFFIC ANALYSIS ZONE SYSTEM

Travel demand models use traffic analysis zones (TAZs) to subdivide the study area for the purpose of connecting land uses to the street network. TAZs represent physical areas containing land uses that produce or attract vehicle-trip ends. Since SCAG is the MPO for the area, the TAZ system for the Santa Monica model was developed to nest within SCAG's TAZ system. After reviewing the TAZ layer used in the SCAG regional model, along with the street network and recent aerial photographs, a set of TAZ boundaries was created for the Santa Monica model to achieve the following local area enhancements:

- Large TAZs were subdivided, allowing for a more detailed assignment of local traffic to the highway network. This level of detail was necessary to forecast traffic volumes at the turning movement level.
- Considerable detail was added to the TAZ system in the downtown street grid to allow for a detailed traffic assignment and a more accurate calculation of the 4D variables (density, diversity of land uses, design of the streetscape, and access to regional destinations).
- TAZs were created to be consistent with large developments such as the Water Garden and Santa Monica Place.

The resulting 2008 model TAZ system includes 824 zones in the model area, of which 599 zones cover the City of Santa Monica and the remaining 225 cover the surrounding areas of the City of Los Angeles. Detailed maps showing the TAZ numbers in all portions of the model area are included in Appendix A.

Also included in the TAZ structure are the external stations or gateways at points where major roadways provide access into the model area. The external gateways represent all major routes by which traffic can enter or exit the study area and capture the traffic entering, exiting, or passing through the model area. Table 2 contains a list of the 22 external gateways numbered from 1001 to 1022 that were established for this model. Figure 2 illustrates the locations of the external stations.

STREET NETWORK

The street network for the base year conditions is derived from the City's GIS roadway centerline file. The model street network includes all freeways, state highways, arterials, collectors, and local roads within the study area (see Figure 1). These classifications are based on the City's 1984 General Plan circulation element and reflect existing conditions.

The streets shown in Figure 1 are classified in four major categories and form the primary street network that is represented in the model structure. As is typical for urban-area models, the model network focuses on the most used facility types. Residential streets are included as well, not to precisely replicate individual travel patterns but to distribute traffic volumes more realistically. The four major street categories are described below.

Freeways

Freeways are high-capacity facilities that primarily serve longer distance travel. Access is limited to interchanges typically spaced at least one mile apart. Interstate 10 is the freeway that runs directly through the Santa Monica model area.

Highways

Roadways designated as highways are typically State highways that are not limited-access freeways. In Santa Monica, these facilities serve travel between the City and its neighboring jurisdictions. The primary highway in Santa Monica is SR 1 (PCH). Portions of Lincoln Boulevard and Santa Monica Boulevard are also designated as State Routes in Santa Monica. However, these facilities function more like arterials and are coded as such in the model.

Arterials

Roadway segments classified as arterials are major roads that provide connections within the City, between the City and neighboring areas, and through the City (cut-through traffic). Arterials in Santa Monica typically have two lanes in each direction, with travel speeds of 30-35 miles per hour (mph).

Collectors

Collectors are facilities that connect local streets to the arterial and highway system, and may also provide direct access to local land uses. Collectors typically have one lane in each direction, with speeds of 25-30 mph. In Santa Monica, streets that fulfill this purpose but are primarily located in residential areas are called feeders.

For each of its records, the street network database includes a street name, distance, functional class, speed, capacity, and number of lanes. These attributes were checked using maps, aerial photographs, and other data provided by the City. Table 3 shows the initial roadway speeds, lanes and capacities used for each roadway class in the model. Where necessary, these values were then modified to reflect current conditions at specific locations.

For a representative sample of network links, traffic counts for daily, AM peak hour, and PM peak hour have been coded for validating the model. These traffic counts were collected as part of the City's ongoing count program.

**TABLE 3
TYPICAL ROADWAY SPEEDS AND CAPACITIES**

Roadway Classification ¹	Speed (MPH)	Total Through Lanes	Lane Capacity (Vehicles per hour per lane)	Total Facility Capacity (Vehicles per hour)
Freeway	65	4-10	2,000	8,000-20,000
Highway	50	4-6	1,200	4,800-7,200
Arterial	30-35	4	900	3,600
Collector/Feeder	25-30	2	600	1,200
Local	25	2	600	1,200
Ramp	30	1	1,800	1,500
Centroid Connector ²	30	2	10,000	20,000

DESCRIPTION OF THE MODEL CALIBRATION PROCESS

Model calibration is the process by which parameters for the model are determined. These parameters are based on comparing travel estimates computed by the model with actual data from the area being modeled. This section provides a general description of the calibration steps and the adjustments made during the process to achieve accuracy levels that are within Caltrans guidelines.

TRIP GENERATION RATES

Trip generation rates relate the number of vehicle trips going to and from a site to some measure of the intensity of use at the site. Each trip has two ends, a “production” and an “attraction”. By convention, trips with one end at a residence are defined as being “produced” by the residence and “attracted” to the other use (workplace, school, retail store, etc.), and are called “Home-Based” trips. Trips that do not have one end at a residence are called “Non-Home-Based” trips.

There are eight trip purposes used in the Santa Monica model:

1. Home-Based Work (HBW): trips between a residence and a workplace.
2. Home-Based Other (HBO): trips between a residence and any other destination.
3. Non-Home-Based (NHB): trips that do not begin or end at a residence, such as traveling from a workplace to a restaurant, or from a retail store to a bank.
4. School (SCHOOL): trips to and from a school.
5. College (COLLEGE): trips to and from a college.
6. Recreational (REC): trips to and from the beaches and parks.
7. Internal to External Commute Trips (IXHBW): Work trips of model area residents who work outside the model area
8. External to Internal Commute Trips (XIHBW): Work trips of model area employees who live outside the model area.

Trip generation rates are initially defined for total trips and later split by trip purpose, for both productions and attractions.

The most widely used source for individual project vehicle trip generation rates in the transportation planning field is *Trip Generation, 8th Edition* (Institute of transportation Engineers [ITE], 2008). This book contains national averages of trip generation rates for a variety of land uses in what are generally suburban locations. The ITE land use categories tend to be very specific, while model land use categories (accounting for all land use in the City) tend to be more general. ITE rates are appropriate for smaller site specific uses, such as traffic studies for development review, and they can provide a starting point for travel models by capturing the interaction between all land uses in the City. However, the unique local characteristics of Santa Monica require the development of specific trip generation rates for the model.

A traffic impact study uses ITE trip generation rates because, in most cases, the project being examined shares characteristics with the information contained in *Trip Generation, 8th Edition*. In other words, both the traffic impact study and the ITE rates rely on single-use, isolated projects that have plenty of free

parking and little or no interaction with other nearby uses. When assessing the impact of an individual project, the ITE rates are typically appropriate since they can correctly mimic the site being analyzed in the traffic impact study.

The Santa Monica model, on the other hand, generates trips by purpose, and balances productions to attractions. The model also has trip rates calibrated to local conditions and other advanced trip generation features such as the cross classification of dwelling units by vehicle availability. Traffic impact studies rely on ITE trip rates that only vary based on land use type or size. While these trip rates are a valid starting point for model calibration and validation, they have a different purpose and are not necessarily suitable for demand forecasting without customization.

Certain ITE rates are more applicable to Santa Monica model rates because of their comparable level of detail. For example, both ITE and the Santa Monica model have a generic office category. Some ITE rates, however, cannot be used directly because the land use category is not the same as the City's land use classifications. For example, ITE's restaurant categories include high turnover restaurant, fast food restaurant, fast food restaurant with drive-through with seating, fast food restaurant with drive-through and no seating, etc. By necessity, Santa Monica restaurant rates represent a compilation and average of those rates customized to the City. It is important to recognize that ITE rates are also averages, based on driveway counts at multiple locations, so the utilization of average rates within the Santa Monica model is entirely appropriate.

The 2008 trip generation rates were initially based on residential trip generation surveys, the SCAG regional model, the San Diego Association of Governments' (SANDAG) trip generation survey, recently calibrated models in similar areas, and *Trip Generation, 8th Edition*. For example, calibrated trip generation rates from Santa Barbara and West Hollywood were used as a starting point. These areas were selected because they share socioeconomic and land use characteristics with the City of Santa Monica. The rates were then modified to account for local conditions based on counts, production-to-attraction balancing (discussed below), and the difference between ITE and model land use definitions. The final Santa Monica trip generation rates are unique to the Santa Monica model, and they are ultimately based upon the results of successful model calibration and validation.

PRODUCTION/ATTRACTION BALANCING

Local trips (internal-to-internal, or I-I) are trips that both start and end in the study area. One of the basic assumptions of any travel model is that the total number of local trips produced is equal to the total number of local trips attracted. It is logically assumed that if a journey is started somewhere, it must have an ending somewhere else. If the total productions and attractions are not equal, the model will typically adjust the attractions to match the productions, thus ensuring that each departing traveler finds a destination. While it is never possible to achieve a perfect match between productions and attractions prior to the automatic balancing procedure, the existence of a substantial mismatch in one or more trip purposes indicates that either land use inputs or trip generation factors may be in error.

Table 4 summarizes the local trip productions and attractions from the Santa Monica travel model for each trip purpose, prior to the application of the automatic balancing procedure. Guidelines published by Federal Highway Administration's Transportation Model Improvement Program (TMIP) and National Highway Cooperative Research Program (NCHRP) suggest that, prior to balancing, the number of productions and attractions should match to within plus or minus 10% (i.e., the production-to-attraction ratio should be within the range of 0.90 to 1.10). The results shown in Table 4 indicate that the 2008 model meets the published guidelines for all trip purposes.

**TABLE 4
TRIP PRODUCTION TO ATTRACTION RATIOS BY PURPOSE**

Trip Purpose	Production/ Attraction Ratio	Percent of Total Daily Vehicle Trips	
		2008 Santa Monica Model ¹	California ²
Home-Based Work (HBW)	1.00	22%	21%
Home-Based Other (HBO)	1.00	47%	48%
Non-Home-Based (NHB)	1.00	32%	31%
Total		101%	100%

¹ The trip purposes listed are the broad categories applied in most every travel model. The more specific Santa Monica trip purposes are subsets of these broader trip purposes, and have been aggregated here for ease of comparison. IXHBW and XIHBW are subsets of the HBW trip purpose. School, College, and REC are subsets of the HBO trip purpose.

² 2000-2001 California Statewide Household Travel Survey Final Report, June 2002.

Note: May not total 100% due to rounding

Source: Fehr & Peers, 2009.

In addition to production and attraction balancing, the percent of total trips for each purpose were checked for reasonableness. Typical values are provided below:

- HBW¹ trips 18% to 27% of all trips
- HBO trips: 47% to 54% of all trips
- NHB trips: 22% to 31% of all trips

This information, in conjunction with trip generation rate comparisons and trip purpose distributions discussed later in this report, indicates that the trip generation component of the Santa Monica model is performing reasonably.

FURTHER REFINEMENT

In addition to the standard trip generation procedures, certain enhancements were added to the Santa Monica model to better capture local trip making characteristics and provide the ability to test certain policy options for future development scenarios. These enhancements include dividing the model area into four “area types” and cross-classifying multifamily households by auto ownership.

Area Types

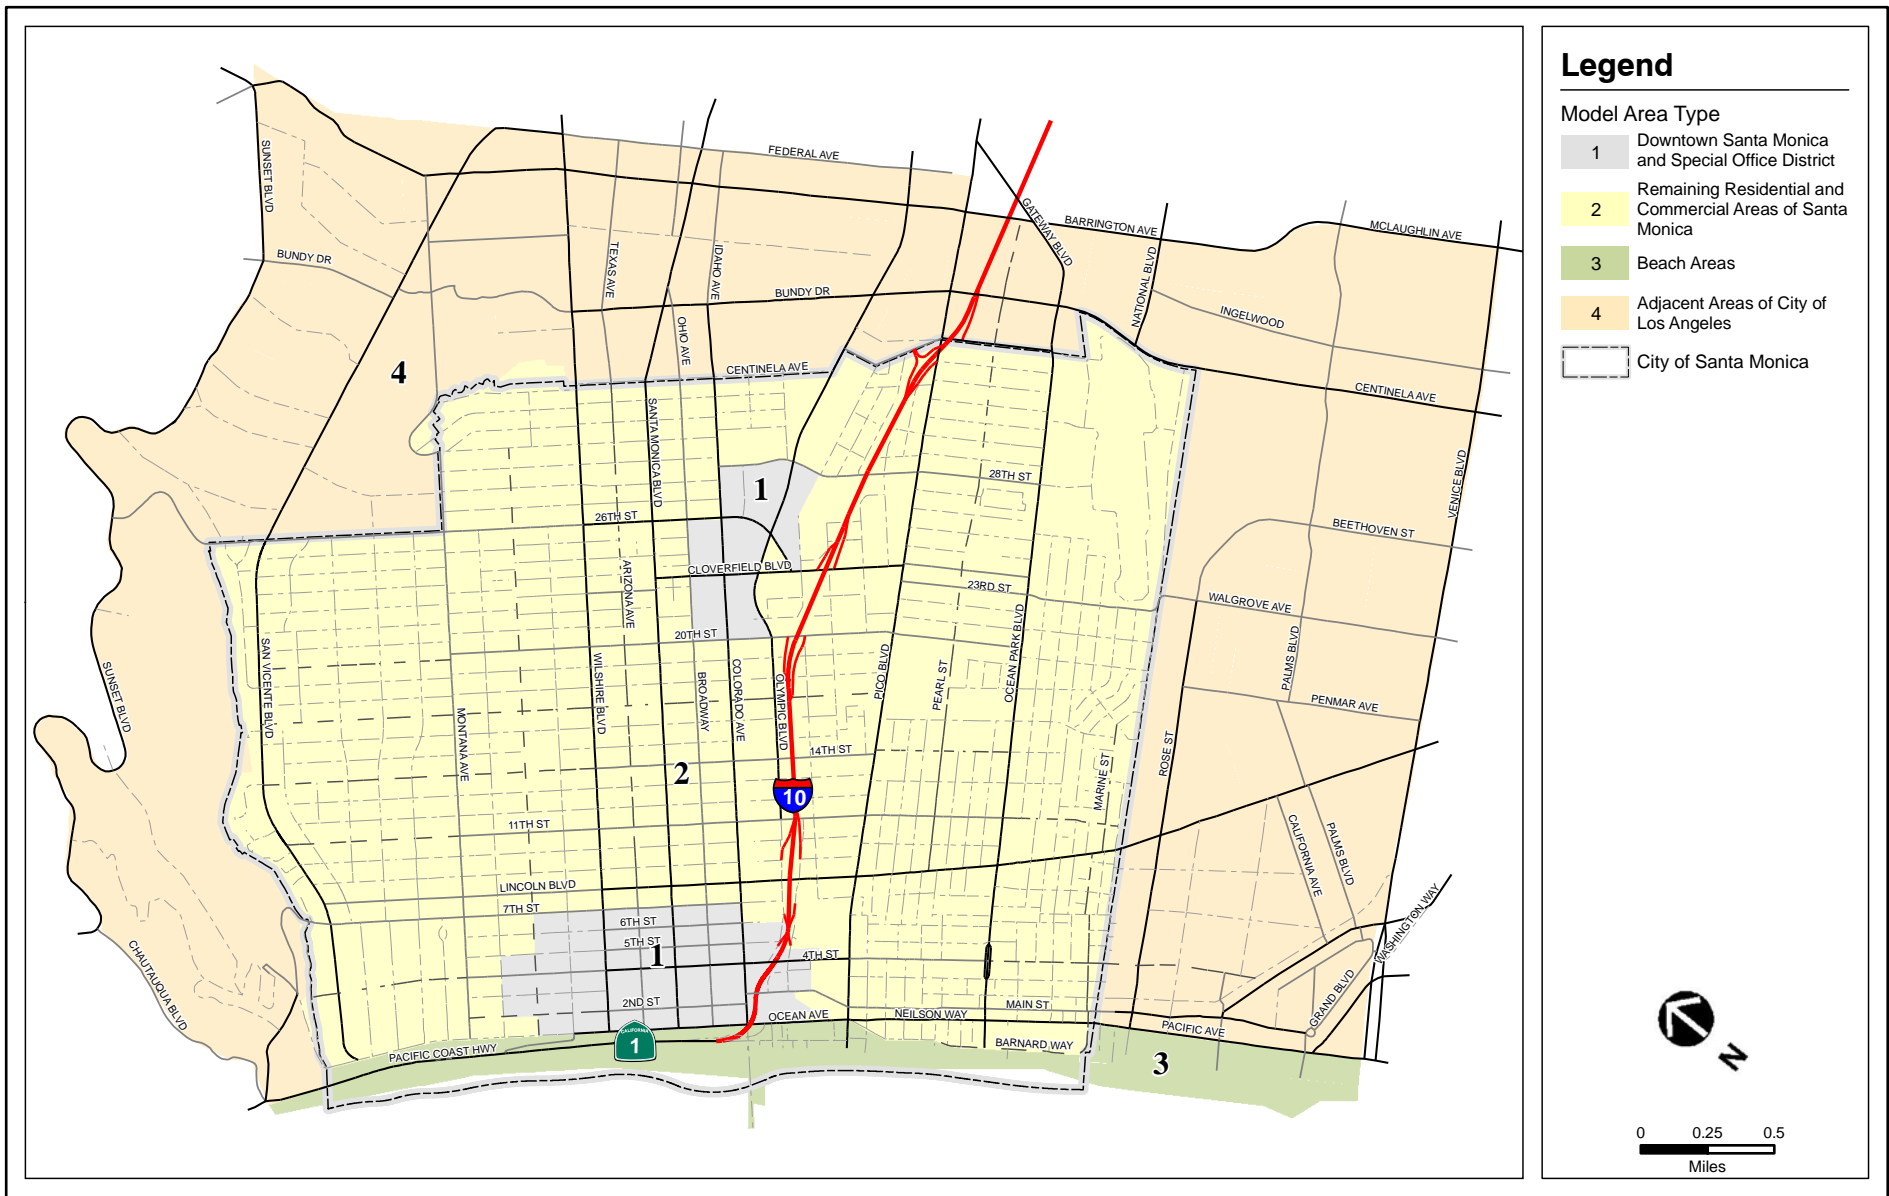

The model area contains a variety of development patterns, each with different land use characteristics and associated trip making patterns. To account for these differences, the model area was divided into four “area types.” The four area types, shown in Figure 3, have their own associated trip generation rates and internal/external trip making characteristics.² Trip generation rates for each land use in each area type are shown in Table 5.

Area type 1 represents Downtown Santa Monica and the Special Office District. This area contains the greatest concentration of commercial and retail land uses within the boundaries of the model. These land uses are grouped together because of their similar density and propensity to attract trips from outside the model area. These two locations differ from the rest of the model area by exhibiting high levels of walkability and a lower propensity for driving. The boundary between area type 1 locations and the rest of the model was based on the likelihood of pedestrian travel between complementary land uses.

Modal choice is strongly determined by auto availability, and since most people arrive in Downtown Santa Monica and the Special Office District by car, the locations covered by area type 1 were defined by two factors that counteracted what otherwise would have been a predisposition towards driving. Distance from parking garages was the first factor. People are more likely to walk than drive when the distance they need to travel is a quarter mile or less. The second factor was a high density of complementary land uses. Driving trips are eliminated when people can park once and walk to multiple destinations.

¹ The trip purposes listed are the broad categories applied in most every travel model. The more specific Santa Monica trip purposes are subsets of these broader trip purposes, and have been aggregated here for ease of comparison. IXHBW and XIHBW are subsets of the HBW trip purpose. School, College, and REC are subsets of the HBO trip purpose.

² Internal/External trip making is explained in the Trip Distribution section below

¹ The ITE manual does not stratify multifamily dwelling units by auto ownership. ITE multifamily rates range from 4.18 to 6.72 depending on the dwelling type. Rates based on auto ownership were developed from National Household Travel Survey (NHTS) data for the City of Santa Monica. NHTS rates range from a minimum of 1.16 to a maximum of 12.52.

² Not all non-residential land use categories are present in each area type. 2008 trip generation rates were only developed for land uses present in 2008 in each area type.

Source: Fehr & Peers, 2009.

Complementary land uses also allow people who do not arrive by car (by way of public transit, biking, walking) to carry out multiple trips within their walking radius.

Area type 2 represents the remaining residential and commercial portion of Santa Monica. This area has development patterns generally consisting of connecting streets, and a mixture of residential and non-residential land uses.

Area type 3 represents the beach areas in the model area. These areas contain a large portion of the recreational land use. Most of the commercial land uses in the area support the recreational land uses. There is limited residential development in area type 3.

Area type 4 represents the areas of the City of Los Angeles surrounding the City of Santa Monica.

Multi-Family Unit Vehicle Ownership

In order to provide the ability to test certain potential policy alternatives, multi-family dwelling units were divided into three types representing varying levels of automobile ownership. Auto-ownership data for each census tract in Santa Monica was obtained from the 2002 National Household Travel Survey, which is conducted by the United States Census Bureau. The total number of multifamily units in each census tract was apportioned to the relevant multi-family trip generation category based on the percentage of households at each level of auto ownership.

TRIP DISTRIBUTION (GRAVITY MODEL)

Once the trip generation step has determined the number of trips that begin and end in each zone, the trip distribution process determines the specific destination of each originating trip. The destination may be within the zone itself, resulting in an intra-zonal trip. If the destination is outside of the zone of origin, it is an inter-zonal trip. Internal-internal (I-I) trips originate and terminate within the model area. Trips that originate within but terminate outside of the model area are internal-external (I-X), and trips that originate outside and terminate inside of the model area are external-internal (X-I). Trips passing completely through the model area are external-external (E-E).

The trip distribution model uses a gravity model equation to distribute trips to all zones. This equation estimates an accessibility index for each zone based on the number of attractions in each zone and a friction factor, which is a function of travel time between zones. Each attraction zone is given its share of productions based on its share of the accessibility index. This process applies to the I-I, I-X, and X-I trips. The E-E trips are added to the trip table prior to final assignment.

Friction Factors

Friction factors, also known as travel time factors, determine the relative attractiveness of each destination zone based on the travel time between TAZs and the number of potential origins and destinations in each TAZ. These factors are used in the trip distribution stage of the model. The 2008 Santa Monica model friction factors are based on data reported in national modeling reference documents such as National Cooperative Highway Research Program (NCHRP) 365, and modified based on local conditions and comparison with the SCAG model. See Appendix B for friction factor curves.

Trips between the Model Area and External Areas

One of the important inputs to a travel model is an estimate of the amount of travel between the study area and neighboring areas outside the model. These are typically called internal-external, or I-X/X-I, trips.

The United States Census Bureau surveys residential and work locations at the place level. Table 6 illustrates the distribution of work locations for Santa Monica residents, while Table 7 illustrates the distribution of residential locations for Santa Monica employees. The census data is specific to Santa Monica, while the model area also encompasses parts of neighboring Los Angeles. It is assumed that a certain percentage of Santa Monica employees who live outside the City of Santa Monica live in the neighboring area of Los Angeles included in the model area.

Based on this data, the proportion of HBW trips entering and leaving the study area was estimated. For non-work trip purposes, information from the SCAG Regional Model was used to develop an initial estimate of the percent of HBO and NHB trips that travel between Santa Monica and other areas. These estimates were then refined using the City's land use database. Table 8 summarizes the proportion of trips by purpose and area type that are assumed to have one end outside the model area.

After the number of I-X/X-I trips was estimated, these trips were distributed to the stations around the perimeter of the model area using external station weights. External station weights were based on counts collected at each external station. The number of through trips at each station was subtracted from the count and the remainder was made up of I-X/X-I trips. The resulting external station weights are presented in Figure 4.

Through Trips

Through trips (also called external-external, or EE trips) are those that pass through the study area without stopping inside the study area. The major flows of through traffic in the Santa Monica area use I-10, PCH and Lincoln Boulevard, with lower volumes of through traffic using other streets. The size of these flows was estimated based on Caltrans traffic counts and the SCAG Regional Model. The through trips were modified in conjunction with the external station weights so that results at the model gateways accurately represented observed data. The resulting through trip matrix is summarized in Table 9.

TRIP ASSIGNMENT

The trip assignment process determines the route that each vehicle trip takes from origin to destination. The model selects these routes in a manner that is sensitive to congestion and the desire of drivers to minimize overall travel time. It uses an iterative, capacity-restrained assignment, and volume adjustments are made that progress towards equilibrium. This technique finds a travel path for each trip that minimizes travel time, while taking into account congestion delays caused by other trips in the model.

The general assignment process includes the following steps.

- Assign all trips to the links along their selected paths.
- After all assignments, examine the volume on each link and adjust its impedance based on the volume-to-capacity ratio.
- Repeat the assignment process for a set number of iterations or until specified criteria related to minimizing travel delays are satisfied.

Source: SCAG

Calibration of the street network included modification of the centroid connectors to more accurately represent the location at which traffic accesses local roads; adjustment of speeds from posted speed limits to reflect the attractiveness of the route and the prevailing speed of traffic; and refinement of turn penalties.

Turn Penalties

Turn penalties are used to prohibit or add delay to certain turning movements. The Santa Monica model prohibits traffic from getting off a freeway ramp and then immediately getting back on. The model also prohibits traffic from making turns across impassable medians. In addition, the model does not allow U-turns in order to avoid counter-intuitive traffic routing. Information on prohibited turns was provided by the City and supplemented with field surveys. Turn penalties may be in effect during the entire day, or only during one or both peak periods.

MODEL VALIDATION

Model validation is the term used to describe model performance in terms of how closely the model's output matches existing travel data in the base year. During the model development process, these outputs are used to further calibrate model inputs. The extent to which model outputs match existing travel data validates the assumptions of the inputs.

Traditionally, most model validation guidelines have focused on the performance of the trip assignment function in accurately assigning trips to the street network. This metric is called static validation, and it remains the most common means of measuring model accuracy.

Models are seldom used for static applications; however, by far the most common use of models is to forecast how a change in inputs would result in a change in traffic conditions. Therefore, another test of a model's accuracy focuses on the model's ability to predict realistic differences in outputs as inputs are changed. This method is referred to as dynamic validation. This section describes the highest-level validation checks that have been performed for the Santa Monica model.

STATIC VALIDATION

The most critical static measurement of the accuracy of any travel model is the degree to which it can approximate actual traffic counts in the base year. Caltrans has established certain trip assignment guidelines for models forecasting future year traffic in *Travel Forecasting Guidelines* (California Department of Transportation, November 1992). The validity of the Santa Monica model was tested under daily, AM peak hour, and PM peak hour conditions. Model volumes were compared to existing traffic counts at 198 individual count sites for daily validation, and 560 count sites for AM and PM peak hour validation. The results are shown in Tables 10 and 11.

Link volume results from model runs were examined and checked for reasonableness. Links where model results varied substantially from the observed counts were identified, and the characteristics of these links were reviewed to ensure that the link attributes reflected local operating conditions. In some cases, link characteristics such as speeds were modified to better reflect conditions on the ground.

Comparison Techniques

Travel model accuracy is usually tested using four comparison techniques:

- The volume-to-count ratio is computed by dividing the model volume by the actual traffic count for individual roadways (or intersections) area-wide.
- The maximum deviation is the difference between the model volume and the actual count divided by the actual count.
- The correlation coefficient estimates the relationship between actual traffic counts and the estimated traffic volumes from the model.
- The percent root mean square error (RMSE) is the square root of the model volume minus the actual count squared, divided by the number of counts. It is a measure similar to standard deviation in that it assesses the accuracy of the entire model.

**TABLE 10
RESULTS OF DAILY MODEL VALIDATION**

Validation Item	Criterion for Acceptance	Model Results
Count Locations	N/A	198
% of Links Within Caltrans Standard Deviations	At Least 75%	75%
% of Screenlines Within Caltrans Standard Deviations	100%	100%
2-way Sum of All Links Counted	Within $\pm 10\%$	6%
Correlation Coefficient	Greater than 88%	98%
RMSE	40% or less	24%

2-way Sum of All Links Counted	Within $\pm 10\%$	-6%	5%
Correlation Coefficient	Greater than 88%	95%	94%
RMSE	40% or less	25%	29%

Source: Fehr & Peers, 2009.

Validation Guidelines

For a model to be considered accurate and appropriate for use in travel forecasting, it must replicate actual conditions within a certain level of accuracy. Since it would be impossible for any model to replicate all counts precisely, validation guidelines have been established by Caltrans and other agencies. Key validation standards for daily travel models based on the Caltrans guidelines are summarized below:

- At least 75 percent of the roadway links for which counts are available should be within the maximum desirable deviation, which ranges from approximately 15 to 60 percent depending on total volume (the larger the volume, the less deviation is permitted).
- All of the roadway screenlines should be within the maximum desirable deviation, which ranges from approximately 15 to 64 percent depending on total volume.
- The two-way sum of the volumes on all roadway links for which counts are available should be within 10 percent of the counts.
- The correlation coefficient between the actual ground counts and the estimated traffic volumes should be greater than 88 percent.

Although not stated in the Caltrans standards, an additional Fehr & Peers validation guideline was applied to the Santa Monica model:

- The RMSE should not exceed 40 percent.

DYNAMIC VALIDATION

The traditional approach to the validation of travel demand models is to compare the link volumes for the model's base year to actual traffic counts. This approach provides information on a model's ability to reproduce a static condition. While reproducing these conditions is very important, it is also important to know that the model will produce stable and reasonable results when various inputs such as land use are changed. The following section presents a selection of the dynamic validation results.

Land Use Changes

A basic form of dynamic validation is to vary the amounts of a particular land use type and compare the magnitude and direction of change from the original forecast. Of particular interest are changes in:

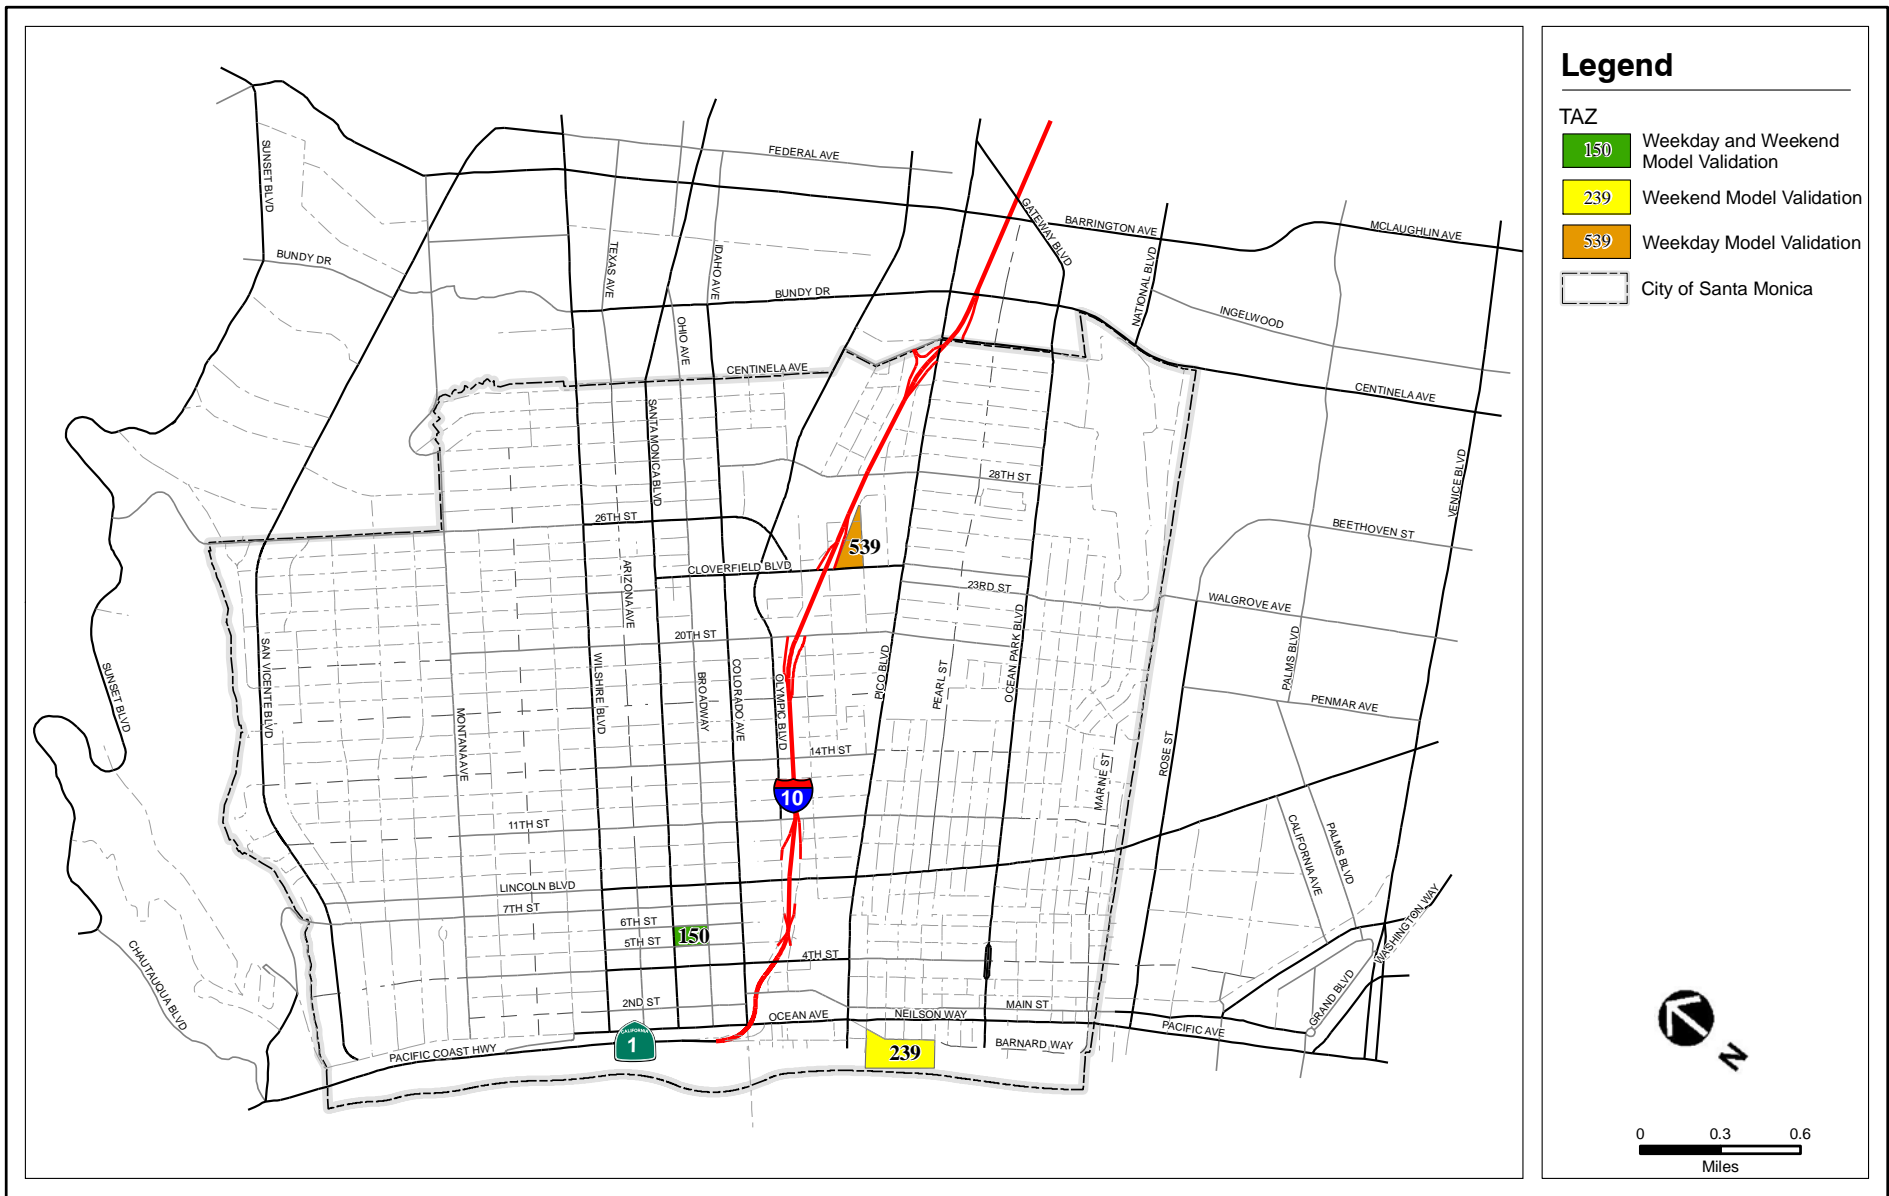

- Vehicle Trips (VT)
- Change in VT per land use unit change (VT/DU or KSF)
- Vehicle Miles Traveled (VMT)
- Change in VMT per land use unit change (VMT/DU or KSF)
- Vehicle Hours Traveled (VHT)
- Change in VHT per land use unit change (VHT/DU or KSF)
- Vehicle miles traveled per vehicle trip (VMT/VT)

This form of dynamic validation was performed on the Santa Monica model by adjusting the number of multi-family one car dwelling units and the retail development in TAZs 150 and 539. These zones were

selected due to their geographic location and the existing land use mix within the zone. To isolate each of these changes, tests were done sequentially, changing one item at a time.

Figure 5 shows the location of the zones that were used for dynamic validation. Zone 150 is located downtown near the intersection of 5th Street and Santa Monica Boulevard and contains a broad mix of residential and non-residential land uses. Zone 539 is located near Clover Park and contains only single-family dwelling units. The values added to a zone were selected based on adjacent land uses. The results are shown in Table 12.

- The change in VT per added DU ranges from 2.7 – 3.2. This is reasonable given the mix of land uses in the various zones and the different trip generation rates of each area type. Within each individual area type there is slight variability, showing stable trip generation across the range of land use magnitudes. The average vehicle trips per added DU are lower for zone 150 due to the abundance of other land uses for the residents to interact with.
- Adding a single DU to the model is a test of how much noise (random error) is in the model. Total VMT changed by between 7 and 25 vehicle miles per day per dwelling unit added, depending on the zone it was added to. Both zones showed a little noise when a single dwelling unit was added. However, both zones perform very well when a realistic quantity of development is added.
- The VHT per DU change is fairly stable around -3.0 to 1.4. There is some noise when adding a single dwelling unit to zone 539. Again, the noise at this extremely small level of change is no longer present for typical increases in the level of development.
- Adding retail land uses to either zone shows a high level of stability and logical results in all metrics. VT/KSF is lower downtown than in the zone near Clover Park, which would be expected given the character of the surrounding area. Similarly, VT/KSF generally declines with an increase in the quantity of retail land use added. Finally, VHT/KSF is greater downtown where travel is generally slower than in other parts of the City.

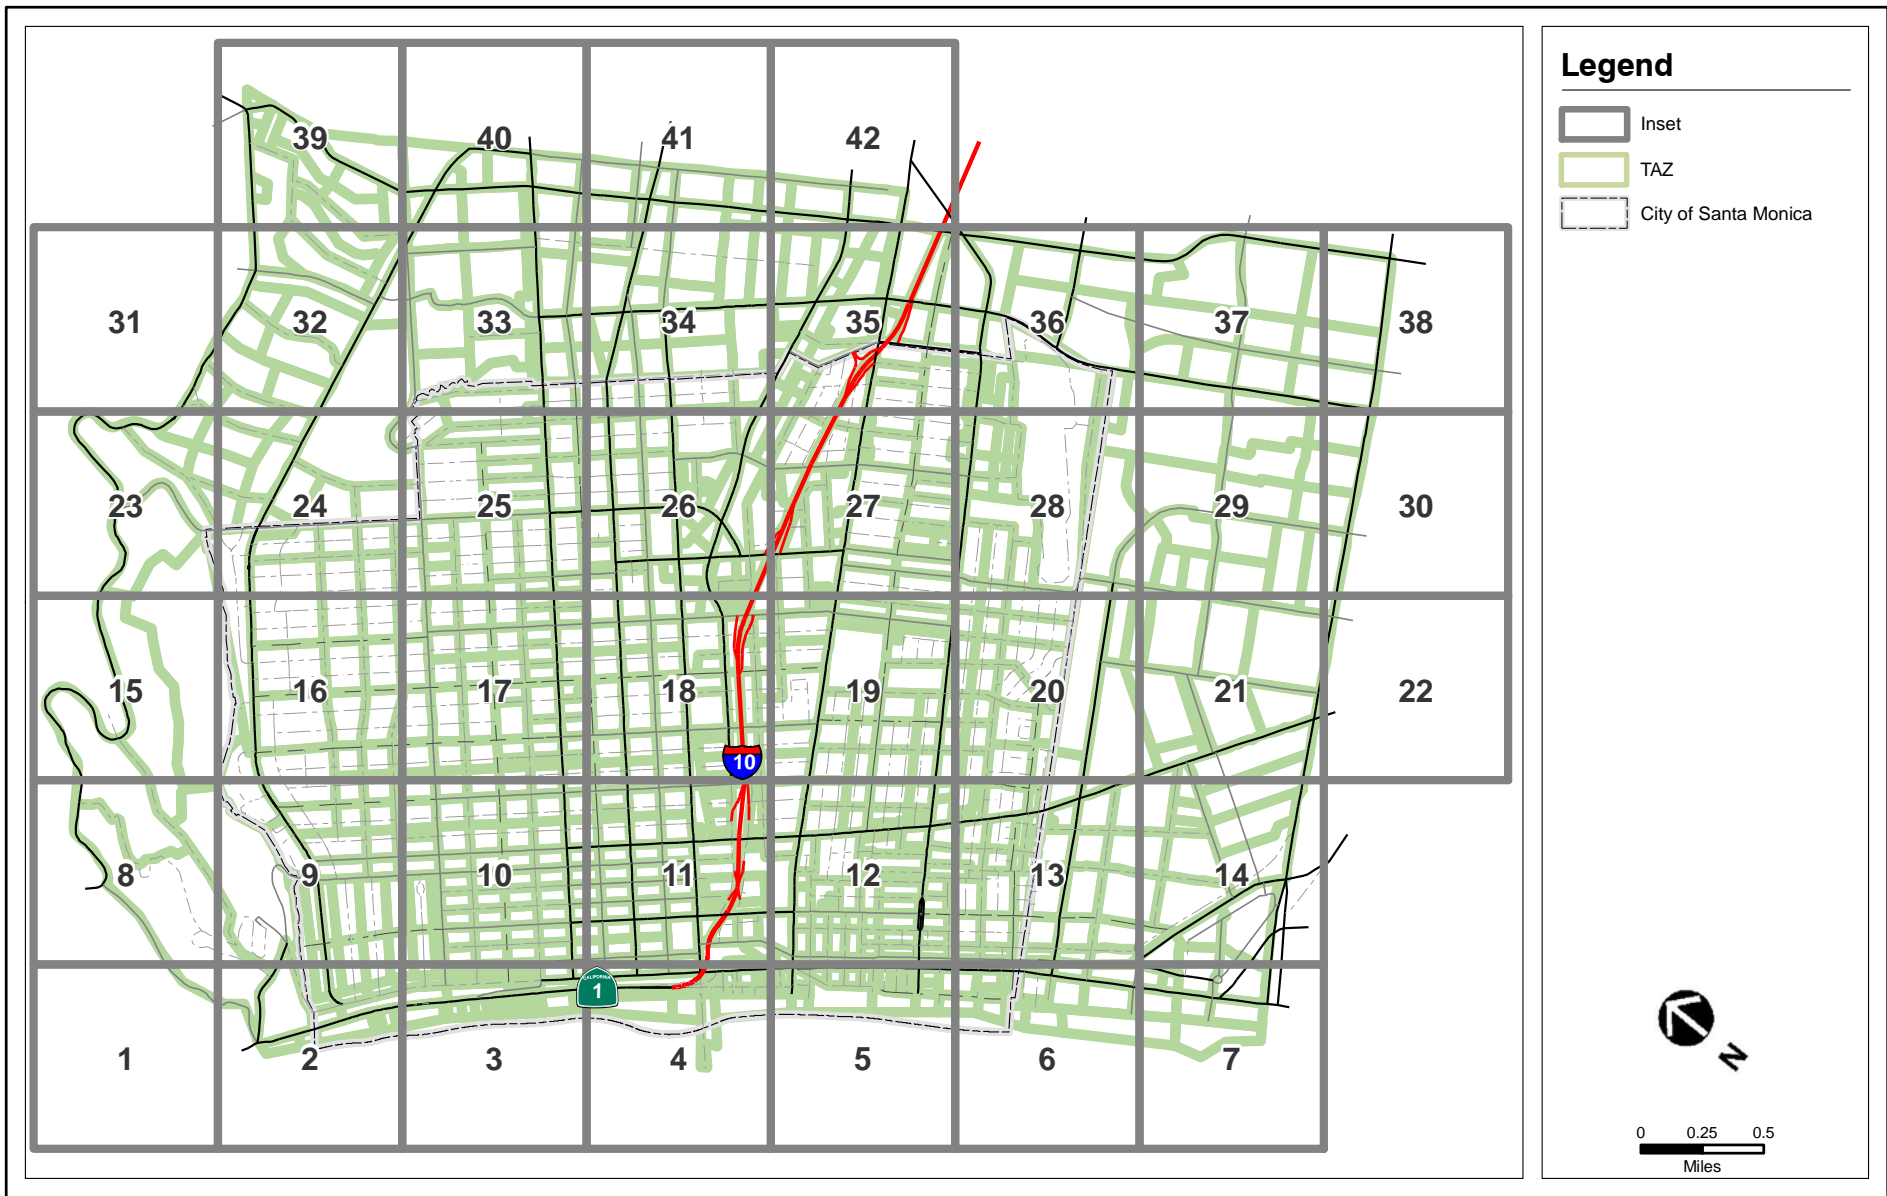

**TABLE 12
RESULTS OF DYNAMIC VALIDATION TESTS**

TAZ	Scenario	Vehicle Trips (VT) ¹	Change in VT/DU or KSF Change	Vehicle Miles Traveled (VMT) ¹	Change in VMT/DU or KSF Change	Vehicle Hours Traveled (VHT) ¹	Change in VHT/DU or KSF Change	VMT/VT

DRAFT MEMORANDUM

Date: April 10, 2015
To: Rachel Kwok, City of Santa Monica
From: Tom Gaul, Jeff Pierson, and Jill Liu, Fehr & Peers

Subject: *City of Santa Monica Travel Demand Forecasting Model Update Report*

Ref: SM13-2611

Fehr & Peers has completed a comprehensive update of the City of Santa Monica's Travel Demand Forecasting Model (TDFM). The base year of the model was upgraded from 2008 to 2013 conditions using network and land use information collected during fall 2013. The TAZ system was also updated to be consistent with the previously expanded TAZ system for the Bergamot Area Plan analysis. New traffic volumes were collected during this period to calibrate and validate the base year model.

The model framework was rewritten to run in an updated version of TransCAD (version 5.0 R4, build 2025). The model structure was also updated to make it easier to manage different scenarios (weekday and weekend) and forecast years (2013, 2025, and 2030). Assignment options can now be selected from directly within the new model interface. In addition, several preparation procedures that were previously calculated outside of the model have been incorporated into the model framework to reduce the number of steps required to run the model.

As part of the model update, Fehr & Peers used the best available tools to prepare and analyze the results from the model. The Southern California Association of Governments (SCAG) 2012 Regional Transportation Plan (RTP) model provided information about the land use and trips outside of the City of Santa Monica. The City's TRAFFIX database, which was used to analyze intersection level of service (LOS), has been upgraded to PTV's VISTRO platform to incorporate more robust signal timing information and to use the *Highway Capacity Manual* (HCM) (Transportation Research Board, 2010) LOS methodology. Finally, the greenhouse gas (GHG) emissions calculations are now done in the latest version of the EMFAC software (EMFAC2011-SG) provided by California Environmental Protection Agency's Air Resources Board.

BACKGROUND

The City of Santa Monica Travel Demand Forecasting Model was originally developed in 2009 to analyze the potential impacts of the 2030 Land Use and Circulation Element (LUCE). The development of and calibration of this model was documented in *Santa Monica LUCE Model Development Report* (Fehr & Peers, December 2009). Since the development of the original 2008 and 2030 weekday models, weekend models as well as several interim year development review models were also developed. The 2030 planning scenario model has also been used to analyze the potential impacts of both the Bergamot Area Plan and the Downtown Specific Plan. Significant network enhancements were made for both of these projects to improve the quality of the model results.

The purposes of this model update were numerous:

- Update the base year of the model to 2013 conditions
- Merge all model years and scenarios into a consistent framework
- Incorporate the latest regional assumptions from the SCAG 2012 RTP
- Upgrade the model interface to run in a more recent version of TransCAD
- Combine all previous model improvements into the base year model
- Streamline the model preparation process to decrease model run time
- Use the latest tools to prepare model inputs and analyze results (TDM+ and EMFAC2011)

BASE YEAR MODEL INPUT DATA

The data that were used as inputs to the updated model were collected in September 2013. Traffic counts were collected during this time by both Fehr & Peers and the City of Santa Monica. The City also provided information on land use and street network changes that had occurred since the 2008 model was developed. Information on land use and street network changes outside the City of Santa Monica was collected from the 2012 SCAG RTP.

Land Use Data

The City of Santa Monica maintains a parcel database with information on existing land use quantities. Fehr & Peers was provided with the changes in land use since the 2008 survey was conducted. The changes include both demolition and construction of new projects. These changes by land use category are shown in Table 1.

In addition to land use within the City of Santa Monica, the model also includes land use information for the neighborhoods bordering the City, within one mile of the city limits. This data is compiled from the most recent version of the SCAG RTP model and was disaggregated to match the Traffic Analysis Zone (TAZ) system in the City's model. The land uses changes for these areas are also shown in Table 1.

TABLE 1. BASE YEAR MODEL LAND USE COMPARISON

Land Use Category	Units	2008	2013	Delta
<i>City of Santa Monica</i>				
Single-family	Dwelling Units	7,584	7,565	-19
Multi-family	Dwelling Units	41,086	41,625	539
Convalescent Care	Dwelling Units	366	366	0
<i>Residential Subtotal</i>	<i>Dwelling Units</i>	<i>49,036</i>	<i>49,556</i>	<i>520</i>
Office	Thousand Square Feet	10,271	10,281	10
Creative Office	Thousand Square Feet	3,483	3,877	394
Government Office	Thousand Square Feet	416	389	-27
Medical Office	Thousand Square Feet	2,058	2,052	-7
Hospital	Thousand Square Feet	958	1,185	226
Retail	Thousand Square Feet	3,485	3,715	230
Personal Services	Thousand Square Feet	2,110	1,939	-171
Cultural	Thousand Square Feet	494	541	48
Entertainment	Thousand Square Feet	765	780	14
Nightlife	Thousand Square Feet	72	53	-19
Restaurant	Thousand Square Feet	1,177	1,240	63
Automotive	Thousand Square Feet	57	55	-2
Lodging	Thousand Square Feet	1,157	1,196	39
Religious	Thousand Square Feet	219	220	1
Police and Fire	Thousand Square Feet	226	226	0
Light Industrial	Thousand Square Feet	1,553	1,547	-5
Heavy Industrial	Thousand Square Feet	142	127	-15
<i>Employment Subtotal</i>	<i>Thousand Square Feet</i>	<i>28,643</i>	<i>29,423</i>	<i>780</i>
K-8 School	Students	8,391	8,391	0
High School	Students	4,148	4,148	0
College	Students	30,000	30,000	0
Airport	Based Aircraft	500	500	0
Recreation	Acres	328	321	-7
<i>Adjacent Neighborhoods</i>				
Residential	Dwelling Units	40,738	40,669	-69
Office	Employees	32,733	30,440	-2,293
Retail	Employees	3,993	3,917	-76
Industrial	Employees	4,585	3,814	-771
Education	Employees	5,854	5,458	-396
<i>Employment Subtotal</i>	<i>Employees</i>	<i>47,165</i>	<i>43,629</i>	<i>-3,536</i>

The land use changes within the City of Santa Monica show a 1 percent increase in dwelling units and a 3 percent increase in employment between 2008 and 2013. For the model area outside of the City, the SCAG 2012 RTP data shows a decrease in the number of dwelling units by less than half a percent and a decrease in the number of employees by 7 percent. This change likely reflects a refinement in how SCAG estimates total employment rather than an indication that the actual number of employees has decreased. Another change not shown in the table is the classification of households in the SCAG model. The 2012 RTP separates single-family and multi-family households for the first time. This information allows a better estimate of the number of vehicle trips generated outside the City since single-family homes generate more vehicle trips than multi-family homes. Combined with the decrease in employment, the net impact of these two changes from the SCAG data is fewer vehicle trips generated in the portion of the model outside the City of Santa Monica.

Traffic Analysis Zone System

Travel demand models use TAZs to subdivide the study area to connect land uses to the street network. TAZs represent physical areas that contain land uses that produce or attract vehicle trips ends. The 2008 model included 599 TAZs in the City of Santa Monica and 225 TAZs for the areas outside of the City. The number of TAZs in Santa Monica was increased to 612 in the 2030 forecast model used to analyze the Bergamot Area Plan.

For this model update, those TAZ changes were replicated in the new 2013 model to provide consistency between the base and future scenarios. The boundaries of TAZs around Tongva Park were adjusted to better align with the development that has occurred since 2008. A single TAZ was also added in this area to separate the land uses north and south of the I-10 freeway. The final number of TAZs that represent the City of Santa Monica in the new 2013 model is 613. The number of TAZs outside the City was unchanged.

Street Network

The model street network includes all freeways, state highways, arterials, collectors, and local roads within the study area. Modifications to the street network were made to incorporate changes that occurred between 2008 and 2013. The final street network used in the model is consistent with the roadway network when traffic counts were collected in September 2013. Any lane reductions or turn restrictions associated with construction activities at that time were included in the model. The network was modified to reflect changes associated with the following projects:

- Construction of Metro Expo Light Rail Line extension along Colorado Avenue
- Median installation along Ocean Avenue between Olympic Boulevard and Pico Boulevard
- Removal of on-street parking to provide a second travel lane on westbound Santa Monica Boulevard between 2nd Street and 5th Street
- Santa Monica Place renovation

Each street in the model is coded with free flow speed, hourly capacity, and the number of lanes. While the land use data and TAZ system are consistent across all scenarios, the attributes of the street network can vary by time of day or day of the week across the five analysis periods in the model:

- Weekday: Daily, AM Peak Hour, and PM Peak Hour
- Saturday: Daily and Midday (MD) Peak Hour

Within the model area, there are only two locations where the number of travel lanes changes throughout the day. There are weekday peak hour parking restrictions on:

- Wilshire Boulevard between Centinela Avenue and Barrington Avenue
- Santa Monica Boulevard between Bundy Drive and Barrington Avenue

Other network attributes are adjusted during the calibration process for each time period to reflect actual conditions at specific locations.

BASE YEAR MODEL CALIBRATION

A travel model is calibrated by adjusting certain parameters to match travel estimates from the model with data from the actual area being modeled. Parameters from the 2008 calibrated model were used as starting points and only adjusted when necessary.

Trip Generation

Trip generation rates relate the number of vehicle trips going to and from a site to some measure of the intensity of use at the site. Each trip has two ends: a production and an attraction. By convention, trips with one end at a residence are defined as being produced by the residence and attracted to the other use (workplace, school, shopping, etc.) and are called home-based trips. Trips that do not have one end at a residence are called non-home-based trips. There are six trip purposes used in the model:

- Home-based work (HBW) trips are between a residence and a workplace
- Home-based other (HBO) trips are between a residence and any other destination
- Non-home-based (NHB) trips do not begin or end at a residence
- School (SCHOOL) trips are to or from a K-12 school
- College (COLLEGE) trips are to or from a college or university
- Recreational (REC) trips are to or from parks and beaches

School, college, and recreational trips are a type of home-based other trip and have been separated in the model to better calibrate those trip purposes. For each land use type, the total daily trips are divided among the six trip purposes. While the trip rates are consistent between the 2008 and 2013 models, the trip purpose percentages were slightly adjusted to balance the total production trip ends and attraction

trip ends for each purpose. Table 2 shows the percent of daily vehicle trips by purpose for both 2008 model and the 2013 model.

TABLE 2. BASE YEAR DAILY TRIP PURPOSE PERCENTAGES

Purpose	2008 Weekday	2013 Weekday	2008 Saturday	2013 Saturday
Home-based work	25%	26%	8%	8%
Home-based other	42%	41%	55%	53%
Non-home-based	27%	26%	28%	28%
School	3%	3%	0%	0%
College	3%	3%	0%	0%
Recreation	1%	1%	9%	10%

The table shows consistent results between the two models, which is expected since only minor changes in land use occurred between 2008 and 2013. In both models, the Saturday scenario has fewer home-based work, school, and college trips than the weekday scenario. There are corresponding increases in home-based other and recreation trips.

Trip generation rates are defined for daily total trips by land use type and then split among the various trip purposes and analysis periods. The model uses different trip rates for the weekday and weekend scenarios. The daily trip generation rates in the 2008 weekday model were developed from a variety of sources. These included residential trip generation surveys, the *Trip Generation, 8th Edition* (ITE, 2008) the 2008 SCAG RTP model, a San Diego Association of Governments (SANDAG) trip generation survey, and other calibrated models within Los Angeles County developed by Fehr & Peers. The daily trip generation rates in the 2008 Saturday model were primarily developed using information from *Trip Generation, 8th Edition*.

After reviewing the daily trip generation rates by land use type, it was determined that no substantial changes had occurred since the rates were initially developed that would justify changing the values for the 2013 model. Tables 3 and 4 show the trip generation rates for the weekday and Saturday scenarios. There are four area types in the model, which allows different trip rates to be assigned based on specific development patterns with different land use characteristics and trip making patterns. Area 1 is Downtown Santa Monica and the Special Office District. Area 2 is the remaining residential and commercial areas of Santa Monica. Area 3 is the coastal area and Area 4 is outside the City of Santa Monica.

Trip Distribution

Trip generation determines the number of trips that begin and end in each TAZ. Trip distribution determines the specific destination of each origin trip. The trip distribution model uses a gravity model equation to distribute trips to all zones. This equation estimates an accessibility index based on the travel time between zones and a friction factor to distribute trips. The friction factor relates the attractiveness between zones to the travel times. These are developed based on information from the SCAG regional model and research from the National Cooperation Highway Research Program (NCHRP).

The gravity model can only be applied to trips which begin and end within the model study area. These are referred to as internal-internal (I-I) trips. Trips which begin or end outside of the model area are referred to as internal-external (I-X) trips or external-internal (X-I) trips. Trips which pass through the model area without stopping are referred to external-external (X-X) trips.

Since the gravity model can only be applied to I-I trips, the number of I-X and X-I trips must be determined before the model can be run. These percentages are determined for each purpose and are based on information from the U.S. Census Bureau and the SCAG regional model. Information from the 2010 Census and the Longitudinal-Employer Household Dynamics (LEHD) Program shows that 20 percent of Santa Monica residents work within Santa Monica and only 14 percent of Santa Monica employees live within Santa Monica. Table 5 shows the final internal (I-I) and external (I-X and X-I) split for all six trip purposes for the 2008 and 2013 weekday and Saturday scenarios.

TABLE 5. BASE YEAR DAILY TRIP DISTRIBUTION PERCENTAGES (INTERNAL/EXTERNAL)

Purpose	2008 Weekday	2013 Weekday	2008 Saturday	2013 Saturday
Home-based work	17% / 83%	16% / 84%	12% / 88%	11% / 89%
Home-based other	31% / 69%	30% / 70%	26% / 74%	25% / 75%
Non-home-based	64% / 36%	62% / 38%	50% / 50%	46% / 54%
School	83% / 17%	81% / 19%	80% / 20%	85% / 15%
College	28% / 72%	28% / 72%	27% / 73%	34% / 66%
Recreation	18% / 82%	16% / 84%	20% / 80%	20% / 80%
All Trips	38% / 62%	37% / 63%	31% / 69%	29% / 71%

The distributions were determined based on several criteria. The initial estimates were based on information from NCHRP and the SCAG regional model. These estimates were further refined to ensure that the all production trip ends have an attraction trip end for internal-internal trips. For example, before balancing, the model area has over 2.5 times more HBW attraction trip ends than production trip ends. The final step in balancing the internal/external splits checks that the total volume at each of the external model gateways matches the observed count data. There are 22 gateways in the model, including the I-10 freeway. External-external trips are determined from the SCAG regional model and are adjusted to ensure consistency with observed count data and internal-external and external-internal trips.

Trip Assignment

The trip assignment process determines the routes that each vehicle trip takes from its origin to its destination. The model assignment algorithm determines paths based on the shortest travel time between two locations, while taking into account congested delays. The model uses an iterative procedure until a specified convergence criterion is met or the total iterations are completed.

Calibration of the street network included adjusting the locations where TAZs connect to the network to more accurately reflect travel behavior and vehicle access points. Free flow speeds and roadway capacities were adjusted to model the attractiveness of given facilities and the prevailing speed of traffic. The adjustments were also based on the presence of design characteristics that may reduce vehicle speeds or capacities such as lane widths, bike lanes, on-street parking, or mid-block crosswalks.

BASE YEAR MODEL VALIDATION

Model validation compares the model's estimated results to observed travel data. During the model development process, this data is used to further calibrate the model inputs. The extent to which model results match observed travel data validates the assumptions of the input parameters.

Static Validation

The most critical static measurement of the accuracy of any travel model is the degree to which it can approximate observed traffic counts during the base year. Caltrans has established certain trip assignment guidelines in *Travel Forecasting Guidelines* (Caltrans, 1992). These requirements are listed below:

- At least 75 percent of the roadway links for which counts are available should be within the maximum desirable deviation, which ranges from 15 percent to 60 percent (the larger the volume, the less deviation permitted)
- All of the roadway screenlines should be within the maximum desirable deviation, which ranges from 15 percent to 64 percent (the larger the volume, the less deviation permitted)
- The two-way sum of the volumes on all roadway links for which counts are available should be within 10 percent of the count volume
- The correlation coefficient between the volumes on all roadway links for which counts are available and the observed counts should be greater than 0.88

Although not stated in the Caltrans guidelines, an additional Fehr & Peers validation requirement is that the percent root mean square error (RMSE) should be less than 40 percent.

Screenlines are boundaries drawn across a street network to determine the total volume crossing the boundary. Screenline accuracy determines whether the volume moving across the model area is consistent with the observed volumes. The following screenlines were used for model validation:

- Marguerita Avenue
- Washington Avenue
- Wilshire Boulevard
- Arizona Avenue
- Santa Monica Boulevard
- Colorado Avenue
- Olympic Boulevard
- Pico Boulevard
- Pearl Street
- Ocean Park Boulevard
- 4th Street
- Lincoln Boulevard
- 14th Street
- Cloverfield Boulevard
- 26th Street
- Bundy Avenue & Centinela Avenue

Three weekday scenarios (daily, AM peak hour, and PM peak hour) and two Saturday scenarios (daily and midday [MD] peak hour) were statically validated. The validation results are shown in Tables 6 and 7. The number of observed count locations is also shown for each scenario.

TABLE 6. WEEKDAY SCENARIOS VALIDATION RESULTS

Metric	Criterion	Daily	AM Peak Hour	PM Peak Hour
Observed locations	-	217	217	217
Percent of links within max dev.	At least 75%	76%	75%	75%
Percent of screenlines within max dev.	100%	100%	100%	100%
Deviation of two-way sum of all links	Within 10%	5%	7%	9%
Correlation coefficient	Greater than 0.88	0.96	0.93	0.94
Percent RMSE	Less than 40%	22%	30%	32%

TABLE 7. SATURDAY SCENARIOS VALIDATION RESULTS

Metric	Criterion	Daily	MD Peak Hour
Observed locations	-	75	75
Percent of links within max dev.	At least 75%	75%	83%
Percent of screenlines within max dev.	100%	100%	100%
Deviation of two-way sum of all links	Within 10%	6%	1%
Correlation coefficient	Greater than 0.88	0.96	0.94
Percent RMSE	Less than 40%	19%	22%

The results from both tables show that all scenarios are statically validated.

Dynamic Validation

Static validation confirms the ability of a travel model to reasonably reproduce a static (singular) condition. Dynamic validation verifies the models applicability to changes in land use and the street network. The 2008 model was dynamically validated to changes in land use quantities. Since the development of the 2008 model, it has been routinely applied for project specific analyses. These projects have included both land use and network changes. Each of these applications has further proven the model to be dynamically valid for both types on input changes required of a travel model. For these reasons, no further dynamic testing was completed.

BASE YEAR MODEL RESULTS

The Land Use and Circulation Element (LUCE) that was adopted in 2010 established the following metrics to be analyzed for general plan consistency:

- Citywide PM peak hour vehicle trips
- Citywide vehicle miles travelled (VMT) per capita
- Citywide vehicle greenhouse gas (GHG) emissions
- AM and PM peak hour corridor travel times
- AM and PM peak hour intersection level of service (LOS)

The travel model produces the first four metrics and can be used to forecast turning movement volumes for future scenarios to calculate LOS. The results from the 2008 base year weekday model were used to establish baseline conditions for each of the metrics. These same metrics are reported from the new 2013 weekday scenarios.

Citywide PM Peak Hour Vehicle Trips

The 2008 base year weekday PM peak hour model produced 60,100 vehicle trips generated within the City of Santa Monica. These trips either originate from or are destined to a location within Santa Monica, or both. This total includes trips from outside the model area as well as the area outside the City but within the model that originate within or are destined to the City. The new 2013 base year weekday PM peak hour model produced 59,600 trips for the City of Santa Monica, a decline of 1 percent.

There are several factors that contribute to the 1 percent difference in PM peak hour trips generated within the City of Santa Monica. The increases in households and employment within the City generate more trip-ends. However, the decreases in employment in the model area outside the City reduce the number of trips generated in the portion of Los Angeles surrounding the City of Santa Monica. The net impact from these two changes is a slight decrease in trips entering Santa Monica from the model area outside the City. While minor, these differences contribute to the 1 percent difference. These results do

not necessarily indicate that the actual number of trips generated within the City of Santa Monica has decreased from 2008 to 2013.

Citywide Vehicles Miles Travelled

The model calculates daily vehicle miles travelled for all City of Santa Monica trips within the model area. The VMT per capita is calculated using total population and employment. Table 8 shows the VMT calculations for the 2008 and 2013 weekday daily scenarios.

TABLE 8. CITYWIDE VEHICLE MILES TRAVELLED

Scenario	VMT	Population	Employment	Total Service Population (Population + Employment)	VMT per Capita
2008 Weekday	2,038,000	95,247	94,206	189,453	10.8
2013 Weekday	1,970,000	92,484	98,280	190,764	10.3

The VMT estimates in the table above only calculate miles travelled within the model area. The mileage associated with trips after they leave the model is not accounted for in these estimates. As discussed, the estimate of total trips generated within the City decreased, which correlates with the decrease in vehicle miles travelled. VMT also decreases slightly because more trips are internalized within the City of Santa Monica compared with the 2008 weekday results. These trips stay within the model and have their destination within the City instead of the area outside the City.

Santa Monica staff provided an updated population estimate for 2013 that is less than the 2008 estimate. With an increase in employment between 2008 and 2013, the total service population (population and employment) increases by less than one percent. The decrease in VMT per capita (per service population) is thus primarily correlated with lower trip generation in areas outside the City. Again, these reductions do not necessarily indicate that VMT per capita has decreased within the City of Santa Monica between 2008 and 2013.

Citywide Vehicle Greenhouse Gas Emissions

EMFAC is a software tool developed by the California Air Resources Board (CARB) to estimate greenhouse gas emissions from VMT. Since the 2008 model was developed, CARB updated the software from EMFAC2007 to EMFAC2011. This comprehensive update dramatically streamlines the data input process and reduces the number of required inputs. The reported metrics also vary slightly between the two versions of the software.

EMFAC2011 requires total VMT and VMT by 5mph speed bin to estimate GHG emissions. The vehicle average fleet mix for Los Angeles County is included in the software and was used for this analysis. The average speed profile from the model was applied to all vehicles types. Table 9 shows the weekday daily

GHG estimates for the 2008 and 2013 models. 2008 results are calculated in EMFAC2007 and 2013 results are calculated in EMFAC2011.

TABLE 9. CITYWIDE VEHICLE GREENHOUSE GAS EMISSIONS

Scenario	2008 Daily	2013 Daily
EMFAC Vehicle Fleet Analysis Year	2008	2013
Carbon Dioxide (CO ₂) (tons/day)	1,490	1,171
Carbon Dioxide (CO ₂) (Pavley) (tons/day)	-	1,111
Carbon Monoxide (CO) (tons/day)	16.93	7.02
Nitrous Oxides (NO _x) (tons/day)	3.03	1.72
Sulphur Oxides (SO _x) (tons/day)	0.01	0.010
Total Organic Gases (TOG) (tons/day)	2.31	0.83
Reactive Organic Gases (ROG) (tons/day)		0.76
Particulate Matter (<10 microns) (tons/day)	0.13	0.14
Particulate Matter (<2.5 microns) (tons/day)	-	0.070
Gasoline Fuel Consumed (gallons/day)	-	102,239
Diesel Fuel Consumed (gallons/day)	-	15,200

While the total daily VMT estimated by the model decreased by 3 percent, this does not solely account for the magnitude of the differences in GHG results between 2008 and 2013. The reason for the discrepancies is more likely due to changes in the EMFAC software and assumptions internal to the program.

AM and PM Peak Hour Corridor Travel Times

Fifteen corridors throughout Santa Monica have been identified for calculation of travel time during the PM peak hour. The congested travel times from the model provide an estimate of overall corridor travel time; however, the model has not been calibrated or validated to these measurements. The model only calculates link level delay and does not include delay associated with signalized or unsignalized intersections. Table 10 shows the AM and PM peak hour travel times for the selected corridors. Separate travel times are provided for each direction of travel.

TABLE 10. WEEKDAY PEAK HOUR CORRIDOR TRAVEL TIMES (MINUTES)
