1 INTRODUCTION

Purpose

This Health Risk Assessment (HRA) evaluates the potential effects of potential toxic air contaminants from State Route 90 (SR-90) on future residents of the proposed Del Rey Pointe project (the “Project”) in the City of Los Angeles (**Figure 1, Regional and Project Vicinity Map** and **Figure 2, Aerial View of the Project Site**).

The HRA includes three components: 1) Emissions inventory; 2) Dispersion modeling, and 3) Health risk calculations. Emissions from SR-90 were calculated using traffic data from the California Department of Transportation (Caltrans) Performance Measurement System (PeMS) database and emission factors from the California Air Resources Board (CARB) EMFAC model. Dispersion modeling was performed using the U.S. Environmental Protection Agency (U.S. EPA) AERMOD model with meteorological data from the closest monitoring station (located at Los Angeles International Airport [LAX]) operated by the South Coast Air Quality Management District (SCAQMD). Sensitive receptors used for modeling were assumed at the location of the proposed project. Health risk calculations were performed using the CARB Hotspots Analysis and Reporting Program (HARP), version 2 Risk Assessment Standalone Tool (RAST).

Project Description

The Project is a residential development in the Palms-Mar Vista-Del Rey Community Plan Area of the City of Los Angeles. The Project site consists of three parcels totaling approximately 2.98 acres. The Project involves the construction of 236 residential units adjacent to the SR-90 freeway. As illustrated in **Figure 2, Aerial View of the Project Site**, the Project site is located approximately 100 feet to the south of SR-90.

Construction of the Project would be completed in 2020, which is when the HRA assumes operation and habitation of the site would begin.

Existing Air Quality Conditions

The SCAQMD’s Multiple Air Toxics Exposure Study (MATES-IV) serves as the air toxics study for the South Coast Air Basin. MATES-IV estimated the cancer risk from toxic air contaminants (TACs) by conducting a comprehensive monitoring program, updated emissions inventory of TACs, and modeling that characterizes health risks for residents in the Basin. The study concluded that the average carcinogenic risk from air pollution is approximately 420 in one million. Mobile sources (e.g., cars, trucks, trains, aircraft) are the greatest contributors. Approximately 75 percent of risk is attributable to diesel particulate emissions, with 20 percent to other toxics associated with mobile sources (e.g., benzene butadiene, formaldehyde), and five percent to stationary sources.

The MATES-IV study included maps that show regional trends in estimated outdoor inhalation cancer risk from toxic emissions. The maps illustrate the number of potential cancers per million persons living a lifetime of breathing (24 hours per day for 70 years). The MATES-IV interactive map is a dynamic tool to depict such risk and illustrates that risk from air toxics can be greater near sources of diesel fuel combustion, such as freeways, airports, and water ports.

2 REGULATORY SETTING AND SIGNIFICANCE THRESHOLDS

Regulatory Settings

The U.S. EPA, CARB, and SCAQMD monitor and regulate TACs, which are defined by California Health and Safety Code Section 39655 as "...any air pollutant which may cause or contribute to an increase in mortality or in serious illness, or which may pose a present or potential hazard to human health. A substance that is listed as a hazardous air pollutant pursuant to subsection (b) of Section 112 of the federal act (42 U.S.C. Sec. 7412(b)) is a toxic air contaminant."

TACs are a diverse group of air pollutants capable of causing chronic (i.e., long duration) and acute (i.e., short duration) adverse effects on human health. TACs include organic and inorganic chemical substances that are emitted from sources including gasoline stations, motor vehicles, dry cleaners, and industrial facilities. TACs differ from criteria pollutants in that ambient air quality standards have not been established for TACs, largely because there are hundreds of TACs, with health effects generally occurring at a local scale.

In 1998, the California Environmental Protection Agency (CalEPA) identified diesel exhaust particulate matter (DPM) as a TAC based on its potential to cause cancer, premature death, and other health problems. The greatest potential for TACs during most construction activities is from combustion of fuel from diesel off-road equipment. The greatest potential during long-term operations is from use of heavy-duty diesel trucks and stationary generators that use diesel fuel.

The City of Los Angeles has considered the implications of locating residences near freeways, and has prepared an advisory notice to alert the public to consider health implications of projects adjacent to freeways that are used by heavy-duty diesel trucks.¹ The City advises that appropriate buffers are provided to protect sensitive uses from being located near such freeways.

The City advises that projects requiring an Environmental Impact Report (EIR) that place sensitive receptors within 1,000 feet of a freeway perform an HRA as a supplemental technical report. An HRA provides information about localized health effects and allows the City to make an informed decision about appropriate site planning and design. This allows the City to consider appropriate mitigation, including enhanced air filtration systems for indoor spaces, building orientation, use of inoperable windows, and other site-specific measures.

This HRA determines the proposed project's potential exposure of humans to TACs from the operation of diesel-fueled vehicles on the SR-90 freeway, the resulting DPM emissions, and the effects of these emissions on cancer and non-cancer chronic health risk. Worksheets are included as an Appendix to this report.

¹ City of Los Angeles Planning Commission, "Advisory Notice to Applicants – Addendum to January 26, 2012 Report." October 2012.

Thresholds of Significance

The SCAQMD establishes that a project could result in significant impacts if it exposes sensitive receptors to an incremental cancer risk of 10 in a million or more, or a non-cancer chronic health risk hazard index (HI) rating of greater than 1.0.² The City's Advisory Notice does not establish thresholds of significance. However, the City's CEQA Thresholds Guide uses the same threshold established by the SCAQMD: an incremental cancer risk of 10 in a million or more.

As a result, this HRA considers that the proposed project could have a significant impact on air quality if it exposes future residents to an incremental cancer risk of 10 in a million or more, or an HI rating of greater than 1.0.

3 METHODOLOGY

Source Identification

Caltrans, Division of Traffic Operations, collects and maintains traffic volume counts for vehicles traveling along the California state highway system. Consistent with SCAQMD recommendations, the roadway segment length analyzed in this study was based on the freeway segment located within an approximate 0.25-mile radius of the project site. **Table 1** presents the annual average daily traffic volumes (AADT) and peak hour traffic volumes associated with the segment of SR-90 considered in this assessment.

Roadway Segment	Post Mile	Total AADT	Truck AADT
Los Angeles, Culver Boulevard	1.746	75,000	2,835

Source: Caltrans, 2015.

To calculate emissions resulting from future project years, a growth factor of 1.0303³ was applied to each subsequent year of traffic after the year 2015 through 2050.

Emissions Calculations

Vehicle traffic and speed data from the Caltrans PeMS database was used for 2015. Hourly traffic data was also used to account for temporal variation of traffic flow. As discussed above, an annual traffic growth rate of 1.0303 percent was then applied to account for future traffic flow.

This HRA uses emission factors from CARB's EMFAC 2014 model. EMFAC was run for years 2020 through 2050 to identify average DPM emission factors from heavy-duty diesel trucks that travel the SR-90 freeway over the lifetime of the proposed project's operation. Vehicle emission factors were calculated

assuming exposure of 30 years. Vehicle emissions were calculated for each year from 2020 (year of project operation) through 2050 based on average traffic flow and vehicle speeds along the study segment for the 30-year risk scenario. Because EMFAC does not provide emission rates past the year 2050, this analysis conservatively applies the 2050 emission rates for the years 2050 through 2090 for the 70-year risk scenario.⁴

Dispersion Modeling

Dispersion modeling was performed using the AMS/EPA Regulatory Model (AERMOD), version 9.3.0. Consistent with SCAQMD recommendations, the roadway segments for this assessment were modeled as line sources represented by separated volume sources. A Cartesian grid of receptors was used for the central portion of the project site, with several discrete receptors placed near the corners of the site to represent ground level receptors. Meteorological data from the SCAQMD LAX monitoring station was imported from the SCAQMD online database.

Carcinogenic Risk Calculations

Cancer risk was calculated using CARB's HARP2 model that was released in March 2015. HARP incorporates the current guidance for conducting HRAs from the California Office of Environmental Health Hazard Assessment (OEHHA). OEHHA recommends that exposure duration (residency time) of 30 years be used to estimate individual cancer risk for the maximally exposed individual resident (MEIR).⁵ OEHHA also recommends that the 30-year exposure duration be used as the basis for public notification and risk reduction audits and plans. 30-year exposure duration starts in the third trimester to accommodate the increased susceptibility of exposures in early life.⁶ Exposure durations of 9-year and 70-year are also presented to illustrate the range of potential cancer risk based on residency periods. The 9-, 30-, and 70-year exposures are chosen to coincide with the US EPA estimates of the average (9-year), high-end (30-year), and lifetime (70-year) residency time.

Carcinogenic compounds are not considered to have threshold exposure levels, meaning any exposure will have some associated risk. Incremental health risks associated with exposure to carcinogenic compounds is defined as the probability of developing cancer as a result of exposure to a chemical at a given concentration. Under a deterministic approach (i.e., point estimate methodology), the cancer risk probability is determined by multiplying a chemical's annual concentration by its unit risk factor (URF). The URF is a measure of the carcinogenic potential of a chemical when a dose is received through the inhalation pathway. It is an upper bound estimate of the probability of contracting cancer from continuous exposure to an ambient concentration of one microgram per cubic meter (ug/m³) over a 70-year lifetime. The URFs in the assessment and the corresponding cancer potency factors (CPFs) were obtained from OEHHA guidance.

⁴ Future automobiles are anticipated to have more advanced air emission control technology, resulting in lower emission rates in subsequent years.

⁵ OEHHA, *Air Toxics Hot Spots Program Guidance Manual for the Preparation of Risk*, February 2015.

⁶ Ibid.

For the inhalation pathway, the cancer risk characterization procedure requires the incorporation of several discrete variables to quantify potential dose. Once determined, contaminant dose is multiplied by the CPF in units of inverse dose expressed in milligrams per kilogram per day (mg/kg/day)⁻¹ and other exposure factors to derive the cancer risk estimate. Therefore, to accommodate the unique exposures associated with the proposed population, the following dose algorithm was used:

$$CDI = (C_{AIR} \times [BR/BW] \times A \times EF)$$

Where:

CDI	=	Chronic daily intake (mg/kg/day)
C _{AIR}	=	Concentration of contaminant (mg/m ³)
BR/BW	=	Daily breathing rate normalized to body weight (l/kg body weight-day)
EF	=	Exposure frequency (days/year)
A	=	Inhalation absorption factor (unitless)

This HRA uses OEHHA-recommended default values for the parameters listed above. The daily breathing rate (BR/BW) was based on OEHHA guidance that varies depending on age, as illustrated in **Table 2**. The recommended exposure frequency (EF) is 350 days per year, which is equivalent to 0.96 (350/365 days per year). The inhalation absorption factor (A) is assumed to be 1 for inhalation-based risk assessment.⁷

Once dose is calculated, cancer risk is estimated by accounting for cancer potency of the pollutant, age sensitivity, exposure duration, averaging time for lifetime cancer risk, and fraction of time spent at home (sensitive receptor). The CPF is specific for each pollutant and is determined through peer-reviewed scientific studies. OEHHA has determined that DPM has a unit risk factor of 3.0E-4 (ug/m³) and a slope factor of 1.1 (mg/kg-day)⁻¹.⁸ The Age Sensitivity Factor (ASF) accounts for greater susceptibility in early life, starting from 3rd trimester of pregnancy to 70 years. The fraction of time at home (FAH) takes into account time actually residing at the sensitive receptor location. FAH also takes into account time spent for all applicable age groups. Exposure duration was assumed to be 30 years, consistent with OEHHA recommendations for residential land uses.

The incremental increase in cancer risk is the product of the dose and pollutant-specific CPF, ASF, ED, and FAH values. Cancer risk is calculated by multiplying the inhalation dose by the inhalation cancer

potency factor to yield the potential excess cancer risk through inhalation. The following equation illustrates the formula for estimating cancer risk. To convert the risk value to chances per million of developing cancer, the potential cancer risk is multiplied by 10⁶.

$$\text{Cancer Risk} = \text{Dose (mg/kg-day)} \times \text{CPF (mg/kg-day)}^{-1} \times \text{ASF} \times \text{ED/AT} \times \text{FAH}$$

Where:

Dose	=	Amount of a pollutant a person is exposed to (mg/kg-day)
CPF	=	Cancer Potency Factor of a pollutant (mg/kg-day) ⁻¹
ASF	=	Age Sensitivity Factor (unitless)
ED/AT	=	Exposure Duration, or how long a person will be exposed to a pollutant in their lifetime (years)/Averaging Time, the duration of which the average dose is calculated (days)
FAH	=	Fraction of time at home (unitless)

As shown in the equation above, each age group has different exposure parameters that require cancer risk to be calculated for each age group. FAH values are presented in **Table 3**.

4 IMPACTS ANALYSIS

Health risk impacts (cancer risk and non-cancer chronic health hazard) were assessed for future on-site residents. **Table 4, Carcinogenic Risks for On-Site Sensitive Receptors**, summarizes the carcinogenic risk for representative receptors located throughout the project site. For carcinogenic exposures, the cancer risk from DPM emissions for the project site resulted in a maximum carcinogenic risk of 8.21 per one million for the 30-year residential exposure scenario. For non-cancer chronic health hazard risk, the HI value is less than 0.01.⁹ It should be noted that the calculated risk assumes no mitigation (such as mechanical filtration) and exposure with windows open. The current City of Los Angeles Building Code requires mechanical filtrations with a Minimum Efficiency Reporting Value (MERV) of 13.¹⁰ This could significantly reduce DPM concentrations at on-site receptors by up to 90%.¹¹ However, differing use by residents can affect this figure, so to provide a conservative analysis, no reduction was assumed.

⁹ The hazard index value is based on the annual average concentration of DPM.

¹¹ SCAQMD, *Pilot Study of High Performance Air Filtration for Classrooms Applications*, October 2009.

Therefore, the actual cancer and chronic health hazard risk impacts to on-site residents would likely be lower than reported below.

5 SUMMARY OF RESULTS

Based on an exposure duration of 30 years, health risk impacts to future on-site residents from exposure of TAC emissions from the SR-90 freeway would not exceed thresholds. As such, no mitigation measures are required. Additionally, the project would comply with the City of Los Angeles Green Building Code which requires mechanical filtration rated MERV 13. The Project would be consistent with the City's Advisory Notice for Freeway-Adjacent Projects.

1. Assumes 1.0303 growth rate factor consistent with the traffic analysis.

2. Section 99.04.504.6 of the Los Angeles Municipal Code requires mechanically ventilated buildings within 1,000 feet of a freeway to provide a Minimum Efficiency Reporting Value (MERV) of 13. This can provide up to 90% reduction in emissions if the HVAC system is constantly running. To remain conservative, this reduction was not built into the model and therefore emissions estimates could be significantly lower depending on the amount of HVAC usage of each unit.

1. Assumes 1.0303 growth rate factor consistent with the traffic analysis.

2. Section 99.04.504.6 of the Los Angeles Municipal Code requires mechanically ventilated buildings within 1,000 feet of a freeway to provide a Minimum Efficiency Reporting Value (MERV) of 13. This can provide up to 90% reduction in emissions if the HVAC system is constantly running. To remain conservative, this reduction was not built into the model and therefore emissions estimates could be significantly lower depending on the amount of HVAC usage of each unit.
